1 How to install/compile/execute our code

To install the app simply download the .zip file and extract the files wherever you would like to keep the files.

Our code is written in python so no pre-compilation required. The code can be executed in multiple different ways from command prompt with different arguments;

-n [n] for specifying n-queens, 8 otherwise.

-file [file] file as input for the initial board state, random otherwise.

-maxsteps [steps] the amount queens to move until program should quit looking for a solution, 4000 otherwise.

Ex:

To compile random 8-queens examples:

```
python n-queens.py
```

To compile random n-queens

```
python n-queens.py -n 'n-value here'
```

To compile random n-queens

```
python n-queens.py -file 'file name here'
```

The format for the input file are as follows; a single digit per line representing the row for the queen. The queens are then filled in from descending order of the text file into the furthest left column of the board all the way to the furthest right in order.

2 Design and Implementation choices

We used structures like numpy arrays and dictionaries to improve performance. We also created two classes One called Queen which contains two variables; row and col for the row and column value respectively. And Puzzle which contains an array of type Queen which contains all the queens on the belonging to the current board state named 'queens' an array of type queens which contains all the queens currently attacking another queen and a count of all attacking pairs of queens.
